## 2 Introduction

### 2.1 Motivation

## 3 Merkle Tree

### 3.1 Incremental Merkle Tree

An Incremental Merkle Tree (IMT) is a Merkle Tree (MT) designed to be updated efficiently.

### 3.2 Binary Tree

A Binary Tree is a tree data structure in which each node has at most two children, referred to as the left child and the right child.

TODO: Explain what is a Merkle tree and an Incremental Merkle Tree.

## 4 LeanIMT

### 4.1 Definition

The **LeanIMT** (Lean Incremental Merkle Tree) is a Binary IMT.

The LeanIMT has two properties:

1. Every node with two children is the hash of its two child nodes.
2. Every node with one child has the same value as its child node.

The tree is always built from the leaves to the root.

The tree will always be balanced by construction.

In a LeanIMT a node is either a leaf or a parent.

Example of a LeanIMT

$T$  - Tree

$V$  - Vertices (Nodes)

$E$  - Edges (Lines connecting Nodes)

$$T = (V, E)$$

$$V = \{a_0, a_1, a_2, H_0, H_1, H_2\}$$

$$E = \{(a_0, H_0), (a_1, H_0), (a_2, a_2), (H_0, H_1), (a_2, H_1)\}$$

## 4.2 Insertion

There are two cases:

1. When the new node is a left node.
2. When the new node is a right node.

We will always see one of these cases in each level when we are inserting a node. It is like, when you insert a node, if that node is left node, the parent node which is in the next level, will be the same node. If it is a right node the parent node, will be the hash of this node with the node in its left. This algorithm will be the same in each level, not only in level 0.

### Case 1: The new node is a left node

It will not be hashed, it's value will be sent to the next level.

If we add  $a_4$ .

$$T = (V, E)$$

$$V = \{a_0, a_1, a_2, a_3, H_0, H_1, H_2\}$$

$$E = \{(a_0, H_0), (a_1, H_0), (a_2, H_1), (a_3, H_1), (H_0, H_2), (H_1, H_2)\}$$

*Before inserting  $a_4$*

*After inserting  $a_4$*

## Case 2: The new node is a right node

If we add  $a_5$ .

*Before inserting  $a_5$*

*After inserting  $a_5$*

#### 4.2.1 Pseudocode

---

**Algorithm 1** LeanIMT Insert algorithm

---

```

1: procedure INSERT(leaf)
2:   if depth < newDepth then    ▷ newDepth is the new depth of the tree
   after inserting the new node
3:     add a new empty array to nodes    ▷ Add a new tree level
4:   end if
5:   node ← leaf
6:   index ← size    ▷ The index of the new leaf equals the number of leaves
   in the tree.
7:   for level from 0 to depth - 1 do
8:     nodes[level][index] ← node
9:     if index is odd then    ▷ It's a right node
10:      sibling ← nodes[level][index - 1]
11:      node ← hash(sibling, node)
12:     end if
13:     index ←  $\lfloor \text{index}/2 \rfloor$     ▷ Divides the index by 2 and discards the
   remainder.
14:   end for
15:   nodes[depth] ← [node]    ▷ Store the new root at the top level
16: end procedure

```

---

#### 4.2.2 Correctness

The idea is to prove that after inserting a new node to the LeanIMT, the tree keeps all the properties.

The Mathematical Induction method will be used to prove the correctness of the algorithm.

*n*: Number of leaves

*T*: LeanIMT Tree

*n* = 0

If the tree is empty, the Insert function returns a new node with the value of the leaf. This satisfies the LeanIMT rproperties because the node does not have children. (Trivial case)

$n \Rightarrow n + 1$

Let's assume that with *n* nodes, the tree *T* is a correct LeanIMT and prove that with *n* + 10 nodes, *T* is still a correct LeanIMT. (Inductive step)

The new node is always added at the end of the list of nodes.

To insert a new node, there are two possible cases:

1. When the new node is a left node
2. When the new node is a right node

Case 1

If the new node is a left node, it means that there were an even number of nodes.

Then, since it's a left node, the parent has only one child and the parent has the same value as the child which is the new node. Then all the ancestors will be constructed following the two properties of the LeanIMT.

Since  $T$  was a correct LeanIMT with  $n$  nodes and inserting a new node that is a left node follows the properties of the LeanIMT  $\Rightarrow$  the entire tree  $T$  is still a correct LeanIMT.

Case 2

If the new node is a right node, it means that there were an odd number of nodes.

Since it is a right node, the value of the parent will be the hash of the left child with the right child which is the new node. Then all the ancestors will be constructed following the two properties of the LeanIMT.

Since  $T$  was a correct LeanIMT with  $n$  nodes and inserting a new node that is a right node follows the properties of the LeanIMT  $\Rightarrow$  the entire tree  $T$  is still a correct LeanIMT.

Then for the two cases 1 and 2 the Insert algorithm follows the LeanIMT properties  $\Rightarrow$  the Insert algorithm is correct.

#### 4.2.3 Time complexity

$n$ : Number of leaves.

The time complexity of the Insertion function is  $O(\log n)$ .

Every time a new node is added is necessary to update or add ancestors until the root of the tree.

### 4.3 Batch Insertion

Performing the insertion in bulk rather than individually using a loop can lead to significant performance improvements because the number of hashing operations is reduced.

When inserting  $n$  members, all levels will be updated  $n$  times if the batch insertion function is not being used.

The core idea behind the batch insertion algorithm is to update each level only once even if there are many members to be inserted.

The algorithm will go through the nodes that are necessary to update the next level of the tree. The other nodes in the tree will not change.

Insert  $a_4$  and  $a_5$ .

Before inserting  $a_4$  and  $a_5$

After inserting  $a_4$  and  $a_5$

#### 4.3.1 Pseudocode

---

##### Algorithm 2 LeanIMT InsertMany algorithm

---

```

1: procedure INSERTMANY(leaves: List of nodes)
2:    $startIndex \leftarrow \lfloor size/2 \rfloor$   $\triangleright$  Divides the size of the tree by 2 and discards
   the remainder.
3:   Add leaves to the tree leaves
4:   for level from 0 to depth - 1 do
5:      $numberOfNodes \leftarrow \lceil nodes[level].length/2 \rceil$   $\triangleright$  Calculate
     the number of nodes of the next level.  $numberOfNodes$  will be the smallest
     integer which is greater than or equal to the result of dividing the number
     of nodes of the level by 2.
6:     for index from  $startIndex$  to  $numberOfNodes - 1$  do
7:        $rightNode \leftarrow nodes[level][index * 2 + 1]$   $\triangleright$  Get the right node if
       exists.
8:        $leftNode \leftarrow nodes[level][index * 2]$   $\triangleright$  Get the left node if exists.
9:       if rightNode exists then
10:         $parentNode \leftarrow hash(leftNode, rightNode)$ 
11:      else
12:         $parentNode \leftarrow leftNode$ 
13:      end if
14:       $nodes[level + 1][index] \leftarrow parentNode$   $\triangleright$  Add the parent node to
      the tree.
15:    end for
16:     $startIndex \leftarrow \lfloor startIndex/2 \rfloor$   $\triangleright$  Divide  $startIndex$  by 2 and discards
    the remainder.
17:  end for
18: end procedure

```

---

#### 4.3.2 Correctness

### 4.3.3 Time complexity

$n$ : Number of leaves in the tree.

$d$ : Tree depth.

$m$ : Number of leaves to insert.

Number of operations when inserting elements in batch:

$$\lceil m \rceil + \lceil \frac{m}{2} \rceil + \lceil \frac{m}{4} \rceil + \dots + \lceil \frac{m}{2^d} \rceil$$

That is the same as  $\sum_{k=0}^d \lceil \frac{m}{2^k} \rceil$

$$\lceil m \rceil \leq m + 1 \text{ then } \lceil \frac{m}{2^k} \rceil \leq \frac{m}{2^k} + 1$$

$$\begin{aligned} \sum_{k=0}^d \lceil \frac{m}{2^k} \rceil &\leq \sum_{k=0}^d (\frac{m}{2^k} + 1) \\ &\leq \sum_{k=0}^d \frac{m}{2^k} + \sum_{k=0}^d 1 \\ &\leq 2m + O(\log(n + m)) \\ &\leq O(m) + O(\log(n + m)) \\ &\Rightarrow \boxed{O(m)} \end{aligned}$$

$$\sum_{k=0}^d \frac{m}{2^k} = m \sum_{k=0}^d \frac{1}{2^k} \approx m * 2 \Rightarrow 2m$$

$$\sum_{k=0}^d \frac{1}{2^k} \text{ (Geometric series)}$$

$$|r| < 1; r = \frac{1}{2}$$

$$\begin{aligned} \sum_{k=0}^{\infty} a * r^k &= \frac{a}{1-r} = \frac{1}{1-\frac{1}{2}} \\ &= \frac{1}{\frac{1}{2}} \\ &= 2 \end{aligned}$$

$$\begin{aligned} \sum_{k=0}^d 1 &= \frac{a}{1-r} = d + 1 \\ &= \log(n + m) + 1 \\ &\Rightarrow O(\log(n + m)) \end{aligned}$$

Then the time complexity of the *InsertMany* function is  $O(m)$ .

### Loop Insertion vs Batch Insertion

The time complexity of the Insertion function using a loop is  $O(\log(n + m))$ .

Going to the root to update or add nodes requires  $\log(n + m)$  number of operations.

If we go to the root to update or add nodes  $m$  times (one time per leaf to add) then we will have:

$$m * \log(n + m) \Rightarrow \boxed{O(m \log(n + m))}$$

$\Rightarrow$  Time complexity Loop Insertion is superlinear:  $O(m \log(n + m))$

$\Rightarrow$  Time complexity Batch Insertion (*InsertMany* function) is linear:  $O(m)$  (linear)

$\Rightarrow$  In terms of time complexity, it is more efficient to use the *InsertMany* function than the *Insert* function in a loop.

### 4.4 Update

There are two cases:

1. When there is no right sibling.
2. When there is right sibling.

#### Case 1: There is no right sibling

Update  $a_4$  to  $a_5$

Before updating  $a_4$

After updating  $a_4$

## Case 2: There is right sibling

Update  $a_2$  to  $a_5$

Before updating  $a_2$  for  $a_5$

After updating  $a_2$  for  $a_5$

### 4.4.1 Pseudocode

---

#### Algorithm 3 LeanIMT Update algorithm

---

```

1: procedure UPDATE( $index, newLeaf$ )
2:    $node \leftarrow newLeaf$ 
3:   for level from 0 to depth - 1 do
4:      $nodes[level][index] \leftarrow node$ 
5:     if index is odd then                                      $\triangleright$  It's a right node
6:        $sibling \leftarrow nodes[level][index - 1]$ 
7:        $node \leftarrow \text{hash}(sibling, node)$ 
8:     else                                                      $\triangleright$  It's a left node
9:        $sibling \leftarrow nodes[level][index + 1]$ 
10:      if sibling exists then                                    $\triangleright$  It's a left node with a right sibling
11:         $node \leftarrow \text{hash}(node, sibling)$ 
12:      end if
13:    end if
14:     $index \leftarrow \lfloor index/2 \rfloor$                               $\triangleright$  Divides the index by 2 and discards the
        remainder.
15:  end for
16:   $nodes[depth] \leftarrow [node]$                                 $\triangleright$  Store the new root at the top level
17: end procedure

```

---

### 4.4.2 Correctness

### 4.4.3 Time complexity

## 4.5 Remove

The *remove* function is the same as the *update* function but the value used to update is 0.

You can use a value other than 0, the idea is to use a value that is not a possible value for a correct member in the list.

Remove  $a_2$

*Before removing  $a_2$*

*After removing  $a_2$*

### 4.5.1 Pseudocode

---

**Algorithm 4** LeanIMT Remove algorithm

---

```
1: procedure REMOVE(index)  
2:   update(index, 0)  
3: end procedure
```

---

### 4.5.2 Correctness

### 4.5.3 Time complexity

## 4.6 Generate Merkle Proof

TODO: Add description with diagrams.

---

**Algorithm 5** LeanIMT generateProof algorithm

---

```
1: procedure GENERATEPROOF(index)
2:   siblings  $\leftarrow$  empty list
3:   path  $\leftarrow$  empty list
4:   for level from 0 to depth - 1 do
5:     isRightNode  $\leftarrow$  index is odd
6:     if isRightNode is true then                                      $\triangleright$  It's a right node
7:       siblingIndex  $\leftarrow$  index - 1
8:     else                                                            $\triangleright$  It's a left node
9:       siblingIndex  $\leftarrow$  index + 1
10:    end if
11:    sibling  $\leftarrow$  nodes[level][siblingIndex]
12:    if sibling exists then
13:      add isRightNode to path
14:      add sibling to siblings
15:    end if
16:    index  $\leftarrow \lfloor \text{index}/2 \rfloor$        $\triangleright$  Divides the index by 2 and discards the
    remainder.
17:  end for
18:  leaf  $\leftarrow$  leaves[index]
19:  index  $\leftarrow$  reverse path and use the list as a binary number and get the
    decimal representation
20:  siblings  $\leftarrow$  leaves[index]
21:  proof  $\leftarrow \{root, leaf, index, siblings\}$ 
22:  return proof
23: end procedure
```

---

**4.6.1 Correctness****4.6.2 Time complexity****4.7 Verify Merkle Proof**

TODO: Add description with diagrams.

---

**Algorithm 6** LeanIMT verifyProof algorithm

---

```
1: procedure VERIFYPROOF(index)
2:   { root, leaf, siblings, index }  $\leftarrow$  proof           $\triangleright$  Deconstruct the proof
3:   node  $\leftarrow$  leaf
4:   for i from 0 to siblings.length - 1 do
5:     isOdd  $\leftarrow$  devide index by 2 i times and check if the result is odd
6:     if isOdd is true then                                 $\triangleright$  node is a right child
7:       node  $\leftarrow$  hash(siblings[i], node)
8:     else                                                   $\triangleright$  It's a left node
9:       node  $\leftarrow$  hash(node, siblings[i])
10:    end if
11:  end for
12:  if root is equal node then
13:    return true
14:  else
15:    return false
16:  end if
17: end procedure
```

---

#### 4.7.1 Correctness

#### 4.7.2 Time complexity

## 5 Implementations

TODO: Explain TypeScript and Solidity implementations.

### 5.1 TypeScript

### 5.2 Solidity

## 6 Benchmarks

## 7 Conslusions

This document is based on the work of [1].
